## Conway triangle symbols

A file of the Geometrikon gallery by Paris Pamfilos

For the sake of these different types, scientific truth should be presented in different forms, and should be regarded as equally scientific, whether it appears in the robust form of vivid colouring of a physical illustration, or in the tenuity and paleness of a symbolical expression.
J.C. Maxwell, Address to the British Association

## 1 Definition, first properties

Conway triangle symbols are called the expressions

$$
\begin{equation*}
S_{A}=\frac{1}{2}\left(b^{2}+c^{2}-a^{2}\right), \quad S_{B}=\frac{1}{2}\left(c^{2}+a^{2}-b^{2}\right), \quad S_{C}=\frac{1}{2}\left(a^{2}+b^{2}-c^{2}\right) . \tag{1}
\end{equation*}
$$

They come from a triangle $A B C$ with side-lengths $\{a, b, c\}$ and angles lying respectively opposite to them: $\{\alpha, \beta, \gamma\}$ [Yiu13a, p.33]. They are equivalent to the expressions

$$
\begin{equation*}
S_{A}=b c \cos (\alpha), \quad S_{B}=c a \cos (\beta), \quad S_{C}=a b \cos (\gamma) . \tag{2}
\end{equation*}
$$

Their importance stems from the fact that they represent the "inner product of displacement vectors" $U-U^{\prime}$, where $\left\{U=(u, v, w), U^{\prime}=\left(u^{\prime}, v^{\prime}, w^{\prime}\right), \ldots\right\}$ are vectors of "absolute barycentric" coordinates, or "barycentrics". Thus,

$$
\begin{equation*}
\left|U U^{\prime}\right|^{2}=S_{A}\left(u-u^{\prime}\right)^{2}+S_{B}\left(v-v^{\prime}\right)^{2}+s_{C}\left(w-w^{\prime}\right)^{2} \tag{3}
\end{equation*}
$$

Figure 1: Triangle $A B C$ with side-lengths $\{a, b, c\}$ and opposite angles $\{\alpha, \beta, \gamma\}$
is the square of the distance of the points in the plane, which are represented by the coordinates vectors $\left\{U, U^{\prime}\right\}$ and

$$
\begin{equation*}
U U^{\prime} \cdot P P^{\prime}=S_{A}\left(u-u^{\prime}\right)\left(p-p^{\prime}\right)+S_{B}\left(v-v^{\prime}\right)\left(q-q^{\prime}\right)+S_{C}\left(w-w^{\prime}\right)\left(r-r^{\prime}\right) \tag{4}
\end{equation*}
$$

represents the inner product of the displacement vectors

$$
U-U^{\prime}=\left(u-u^{\prime}, v-v^{\prime}, w-w^{\prime}\right) \quad \text { and } \quad P-P^{\prime}=\left(p-p^{\prime}, q-q^{\prime}, r-r^{\prime}\right),
$$

where $\left\{U, U^{\prime}, P, P^{\prime}\right\}$ are vectors of absolute barycentrics, satisfying per definition

$$
u+v+w=u^{\prime}+v^{\prime}+w^{\prime}=p+q+r=p^{\prime}+q^{\prime}+r^{\prime}=1 .
$$

Alternatively the inner product and the square distance can be represented using the sidelengths themselves:

$$
\begin{equation*}
\left|U U^{\prime}\right|^{2}=-a^{2}\left(v-v^{\prime}\right)\left(w-w^{\prime}\right)-b^{2}\left(w-w^{\prime}\right)\left(u-u^{\prime}\right)-c^{2}\left(u-u^{\prime}\right)\left(v-v^{\prime}\right) . \tag{5}
\end{equation*}
$$

For more general barycentrics $U=(u, v, w)$ with $u+v+w \neq 1$ we come to "absolute barycentrics" by dividing with

$$
\begin{equation*}
s_{U}=u+v+w \quad \text { giving the absolute barycentric: } \quad U^{*}=\frac{1}{s_{U}} U=\frac{1}{s_{U}}(u, v, w) \tag{6}
\end{equation*}
$$

From their definition, comes not to surprise that these symbols are ubiquitous in subjects of "triangle geometry" dealt with barycentrics ([Yiu13a], [Yiu13b], [Kim18]) (see file Barycentric coordinates).

## 2 Identities resulting directly from definition

Next identities are easy consequences of the definition ([Yiu13a, p.33]). In these the expression

$$
\begin{equation*}
S=2 \Delta=a b \sin (\gamma)=b c \sin (\alpha)=c a \sin (\beta), \tag{7}
\end{equation*}
$$

is twice the area $\Delta$ of the triangle of reference $A B C$ and obviously hold the relations:

$$
\begin{align*}
& S_{A}=S \cot (\alpha), \quad S_{B}=S \cot (\beta), \quad S_{C}=S \cot (\gamma),  \tag{8}\\
& S_{B}+S_{C}=a^{2}, \quad S_{C}+S_{A}=b^{2}, \quad S_{A}+S_{B}=c^{2},  \tag{9}\\
& S_{B}-S_{C}=c^{2}-b^{2}, \quad S_{C}-S_{A}=a^{2}-c^{2}, \quad S_{A}-S_{B}=b^{2}-a^{2},  \tag{10}\\
& S_{A}^{2}=b^{2} c^{2}-S^{2}, \quad \begin{array}{c}
S_{B}^{2}=c^{2} a^{2}-S^{2}, \\
S_{A} S_{B}+S_{B} S_{C}+S_{C} S_{A}=S^{2},
\end{array} S_{C}^{2}=a^{2} b^{2}-S^{2},  \tag{11}\\
& S_{A} S_{B}+S_{B}^{B} S_{C}+S_{C} S_{A}=S^{2},  \tag{12}\\
& a^{2} S_{A}+b^{2} S_{B}+c^{2} S_{C}=2 S^{2},  \tag{13}\\
& a^{2}\left(S_{A}^{2}-S_{B} S_{C}\right)+b^{2}\left(S_{B}^{2}-S_{C} S_{A}\right)+c^{2}\left(S_{C}^{2}-S_{A} S_{B}\right)=0 .  \tag{14}\\
& S_{A} S_{B}+c^{2} S_{C}=S_{B} S_{C}+a^{2} S_{A}=S_{C} S_{A}+b^{2} S_{B}=S^{2}, \tag{15}
\end{align*}
$$

## 3 Connection with the Brocard angle

The Brocard angle $\omega$ of the triangle is defined in two ways, corresponding to the two orientations of the triangle $A B C$. One way to define it is to select the positive orientation and draw lines from the vertices making the same angle $\phi$ with the sides (See Figure 2-I).

Figure 2: Brocard angle $\omega$ of the triangle $A B C$
In general the three resulting lines do not concur. It is proved though that, for a given triangle $A B C$, there is precisely one angle $0<\omega<60^{\circ}$, for which this happens indeed and the three lines concur at a point $B_{1}$. Selecting the negative orientation in the same triangle (See Figure 2-II) and doing the same work produces again, up to orientation, the same angle $\omega$, and a second point $B_{2}$ of concurrence of the three lines. The two points are called "Brocard points" of the triangle and the angle $\omega$ satisfies the remarkable relation to the sides of the triangle, connecting it with the Conway triangle symbols:

$$
\begin{align*}
\cot (\omega) & =\cot (\alpha)+\cot (\beta)+\cot (\gamma) \quad \Rightarrow \\
S_{\omega}:=S \cot \omega & =S_{A}+S_{B}+S_{C}=\frac{1}{2}\left(a^{2}+b^{2}+c^{2}\right) \tag{16}
\end{align*}
$$

The importance of the symbol $S_{\omega}$, defined in the previous line, lies in the possibility to express with it and the symmetric functions of $\{a, b, c\}$ and $\left\{S_{A}, S_{B}, S_{C}\right\}$ all possible "cyclic invariant expressions" involving $\{a, b, c\}$ and $\left\{S_{A}, S_{B}, S_{C}\right\}$. Next delirium calculantis gives a flavour of this fact. The sums appearing in the equations are considered over the cyclic permutations of the letters $\{a, b, c\}$ and $\{A, B, C\}$. Thus, considering the additional symmetric functions in the side-lengths of the triangle

$$
2 s=a+b+c \text { and } R=\frac{a b c}{2 S}
$$

latter proved easily to be the "circumradius", and s called the "half-perimeter" of the triangle, we have:

$$
\begin{align*}
a b+b c+c a & =\frac{1}{2}\left((a+b+c)^{2}-\left(a^{2}+b^{2}+c^{2}\right)\right)=2 s^{2}-S_{\omega} .  \tag{17}\\
a^{3}+b^{3}+c^{3} & =\left(\sum a^{2}\right)\left(\sum a\right)-\sum a b(a+b+c-c) \\
& =\left(2 S_{\omega}\right)(2 s)-\left(2 s^{2}-S_{\omega}\right)(2 s)+3 a b c \\
& =(2 s)\left(3 S_{\omega}-2 s^{2}\right)+6 R S . \tag{18}
\end{align*}
$$

$$
\begin{align*}
& \sum a(b+c)^{2}=\sum a(b+c+a-a)^{2}=\sum a\left((2 s)^{2}-4 s a+a^{2}\right) \\
& =(2 s)^{3}-4 s \sum a^{2}+\sum a^{3}=2 s\left(2 s^{2}-S_{\omega}\right)+6 R S .  \tag{19}\\
& \sum a b(a+b)=\sum a b(a+b+c-c)=2 s \sum a b-3 a b c \\
& =2 s\left(2 s^{2}-S_{\omega}\right)-6 R S \text {. }  \tag{20}\\
& \sum a(b-c)^{2}=\sum a(b+c)^{2}-\sum a(4 b c) \\
& =2 s\left(2 s^{2}-S_{\omega}\right)-18 R S .  \tag{21}\\
& \sum a S_{A}=\frac{1}{2} \sum a\left(b^{2}+c^{2}+a^{2}-2 a^{2}\right)=2 s S_{\omega}-\sum a^{3} \\
& =4 s\left(s^{2}-S_{\omega}\right)-6 R S \text {. }  \tag{22}\\
& \sum a^{4}=\sum a^{2}\left(S_{B}+S_{C}\right)=\sum S_{A}\left(b^{2}+c^{2}\right)=\sum S_{A}\left(\sum a^{2}-a^{2}\right) \\
& =2\left(S_{\omega}^{2}-S^{2}\right) \text {. }  \tag{23}\\
& \sum a^{2} b^{2}=\frac{1}{2}\left(\left(\sum a^{2}\right)^{2}-\sum a^{4}\right)=S_{\omega}^{2}+S^{2} .  \tag{24}\\
& \sum S_{A}^{2}=\left(\sum S_{A}\right)^{2}-2 \sum S_{A} S_{B}=S_{\omega}^{2}-2 S^{2} .  \tag{25}\\
& \sum a S_{A}^{2}=\sum a\left(b^{2} c^{2}-S^{2}\right)=a b c \sum b c-S^{2} \sum a \\
& =2 R S\left(2 s^{2}-S_{\omega}\right)-2 s S^{2} \text {. }  \tag{26}\\
& \sum a^{2} b^{2} S_{C}=\frac{1}{2} \sum a^{2} b^{2}\left(a^{2}+b^{2}+c^{2}-2 c^{2}\right)=S_{\omega} \sum a^{2} b^{2}-3 a^{2} b^{2} c^{2} \\
& =S_{\omega}\left(S_{\omega}^{2}+S^{2}\right)-12 R^{2} S^{2} .  \tag{27}\\
& \sum a^{2} S_{A}^{2}=\sum a^{2}\left(b^{2} c^{2}-S^{2}\right)=3 a^{2} b^{2} c^{2}-S^{2} \sum a^{2}=2 S^{2}\left(6 R^{2}-S_{\omega}\right) \text {. }  \tag{28}\\
& S_{A} S_{B} S_{C}=\frac{1}{3}\left(3 S_{A} S_{B} S_{C}\right)=\sum S_{A}\left(S^{2}-a^{2} S_{A}\right)=S^{2} \sum S_{A}-\sum a^{2} S_{A}^{2}  \tag{29}\\
& =S^{2}\left(S_{\omega}-4 R^{2}\right) \text {. }  \tag{30}\\
& \sum b c S_{B} S_{C}=\frac{1}{2}\left(\left(\sum a S_{A}\right)^{2}-\sum a^{2} S_{A}^{2}\right)=\frac{1}{2}\left(\left(4 s\left(s^{2}-S_{\omega}\right)-6 R S\right)^{2}-2 S^{2}\left(6 R^{2}-S_{\omega}\right)\right) \\
& =8 s R S\left(S_{\omega}-s^{2}\right)+S^{2}\left(2 s^{2}+12 R^{2}-S_{\omega}\right) .  \tag{31}\\
& \sum a^{a} \\
& =\sum a^{2}\left(S_{B}+S_{C}\right)^{2}=\sum a^{2}\left(S_{B}^{2}+S_{C}^{2}+S_{A}^{2}-S_{A}^{2}+2 S_{B} S_{C}\right) \\
& =\left(S_{\omega}^{2}-2 S^{2}\right)\left(2 S_{\omega}\right)+2 S^{2}\left(6 R^{2}-S_{\omega}\right) \\
& =2\left(S_{\omega}^{3}+3 S^{2}\left(2 R^{2}-S_{\omega}\right)\right) \text {. }  \tag{32}\\
& \sum S_{A}^{3} \quad=\sum S_{A}\left(b^{2} c^{2}-S^{2}\right)=\sum b^{2} c^{2} S_{A}-S^{2} \sum S_{A} \\
& =S_{\omega}^{3}-12 R^{2} S^{2} \text {. }  \tag{33}\\
& \sum S_{A}\left(S_{B}^{2}+S_{C}^{2}\right)=\sum S_{A}\left(\sum S_{A}^{2}-S_{A}^{2}\right)=\left(S_{\omega}^{2}-2 S^{2}\right) \sum S_{A}-\sum S_{A}^{3} \\
& =12 R^{2} S^{2}-2 S^{2} S_{\omega} \text {. }  \tag{34}\\
& \sum a^{4} S_{A}=\sum\left(S_{B}+S_{C}\right)^{2} S_{A}=\sum\left(S_{B}^{2}+S_{C}^{2}+2 S_{B} S_{C}\right) S_{A} \\
& =6 S_{A} S_{B} S_{C}+\sum a^{2} S_{A}^{2} \\
& =4 S^{2}\left(S_{\omega}-3 R^{2}\right) \text {. } \tag{35}
\end{align*}
$$

$$
\begin{align*}
\sum a^{3} S_{A}^{2} & =\sum a^{3}\left(b^{2} c^{2}-S^{2}\right)=a^{2} b^{2} c^{2} \sum a-S^{2} \sum a^{3} \\
& =S^{2}\left(2 s\left(2 s^{2}-3 S_{\omega}+4 R^{2}\right)-6 R S\right)  \tag{36}\\
\sum a^{4} S_{A}^{2} & =\sum a^{4}\left(b^{2} c^{2}-S^{2}\right)=a^{2} b^{2} c^{2} \sum a^{2}-S^{2} \sum a^{4} \\
& =2 S^{2}\left(S^{2}+\left(4 R^{2}-S_{\omega}\right) S_{\omega}\right)  \tag{37}\\
\sum S_{A}^{2} S_{B}^{2} & =\sum\left(S^{2}-c^{2} S_{C}\right)^{2}=\sum\left(S^{4}-2 S^{2} c^{2} S_{C}+c^{4} S_{C}^{2}\right) \\
& =3 S^{4}-2 S^{2} \sum c^{2} S_{C}+\sum c^{4} S_{C}^{2} \\
& =3 S^{4}-4 S^{4}+S^{2}\left(S^{2}+8 R^{2} S_{\omega}-2 S_{\omega}^{2}\right) \\
& =2 S_{\omega} S^{2}\left(4 R^{2}-S_{\omega}\right)+S^{4}  \tag{38}\\
\sum a^{4} S_{A}^{3} & =\sum a^{4} S_{A}\left(b^{2} c^{2}-S^{2}\right)=a^{2} b^{2} c^{2} \sum a^{2} S_{A}-S^{2} \sum a^{4} S_{A} \\
& =4 S^{4}\left(5 R^{2}-S_{\omega}\right) \tag{39}
\end{align*}
$$

## 4 Playing with the formulas, GH, GI

Here and in the next sections, we apply the previous formulas to calculate the distances of various remarkable "triangle centers" ([Kim18]) expressed in barycentric coordinates (see file Barycentric coordinates). The result of the computation takes the form of an expression in terms of $\left\{s, R, S, S_{\omega}\right\}$ introduced in the preceding section.

As a first example we calculate the square of the distances $\left\{G H^{2}, G I^{2}\right\}$ between the centroid $G$, the orthocenter $H$ and the incenter $I$ of the triangle. From this and the relation $|H G|=2|G O|$ we obtain also the distance $|G O|$ from the circumcenter $O$.

$$
\begin{align*}
G & =(1: 1: 1), \quad G^{*}=\frac{1}{3}(1: 1: 1) \quad \text { (absolute barycentrics) } \\
H & =\left(S_{B} S_{C}: \ldots\right), \quad H^{*}=\frac{1}{S^{2}}\left(S_{B} S_{C}: \ldots\right) \\
I & =(a: b: c), \quad I^{*}=\frac{1}{2 s}(a: b: c) \\
G H^{2} & =\sum S_{A}\left(\frac{1}{3}-\frac{1}{S^{2}} S_{B} S_{C}\right)^{2}=\frac{1}{9 S^{4}} \sum S_{A}\left(S^{4}-6 S^{2} S_{B} S_{C}+9 S_{B}^{2} S_{C}^{2}\right) \\
& =\frac{1}{9 S^{4}}\left(S^{4} \sum S_{A}-6 S^{2} \sum S_{A} S_{B} S_{C}+9 S_{A} S_{B} S_{C} \sum S_{B} S_{C}\right) \\
& =\frac{1}{9 S^{4}}\left(S^{4} \sum S_{A}-9 S^{2} S_{A} S_{B} S_{C}\right) \\
& =\frac{1}{9 S^{4}}\left(S^{4} S_{\omega}-9 S^{4}\left(S_{\omega}-4 R^{2}\right)\right) \\
& =4\left(R^{2}-\frac{2}{9} S_{\omega}\right) \quad \Rightarrow  \tag{40}\\
|G O| & =\frac{1}{2}|G H| \Rightarrow \quad \Rightarrow O^{2}=R^{2}-\frac{2}{9} S_{\omega} \quad \Rightarrow \quad O R^{2}-2 S_{\omega}  \tag{41}\\
G I^{2} & =\sum S_{A}\left(\frac{1}{3}-\frac{a}{2 s}\right)^{2}=\frac{1}{36 s^{2}} \sum S_{A}(2 s-3 a)^{2} \\
& =\frac{1}{36 s^{2}}\left(4 s^{2} \sum S_{A}-12 s \sum a S_{A}+9 \sum a^{2} S_{A}\right) \\
& =\frac{1}{9 S}\left(s\left(6 s^{2}-5 S_{\omega}\right)-18 R S\right) \tag{42}
\end{align*}
$$

For the four quantities, anticipating a bit the fundamentals of section 6 and using the expressions in terms of the "inradius" $r$ of triangle $A B C$ :

$$
S=2 s r, \quad S_{\omega}=\frac{1}{2}\left(a^{2}+b^{2}+c^{2}\right)=s^{2}-r^{2}-4 r R
$$

we obtain the formulas:

$$
\begin{align*}
G I^{2}=\frac{1}{9}\left(S_{\omega}+6 r(r-2 R)\right) & =\frac{1}{9}\left(s^{2}+5 r^{2}-16 R r\right)  \tag{43}\\
H O^{2}=9 R^{2}-2 S_{\omega} & =2 r^{2}+8 R r+9 R^{2}-2 s^{2},  \tag{44}\\
H G^{2}=4\left(R^{2}-\frac{2}{9} S_{\omega}\right) & =\frac{4}{9} H O^{2},  \tag{45}\\
G O^{2}=R^{2}-\frac{2}{9} S_{\omega} & =\frac{1}{9} H O^{2} . \tag{46}
\end{align*}
$$

## 5 Euler's theorem, Gerretsen's inequalities

The distance $|I O|$ of the incenter $I(a: b: c)$ from the circumcenter $O\left(a^{2} S_{A}, \ldots\right)$ is connected with Euler's theorem, formulated below.

$$
\begin{align*}
O & =\left(a^{2} S_{A}: \ldots\right), \quad O^{*}=\frac{1}{2 S^{2}}\left(a^{2} S_{A}: \ldots\right) \\
I O^{2} & =\sum S_{A}\left(\frac{a}{2 s}-\frac{1}{2 S^{2}} a^{2} S_{A}\right)^{2}=\frac{1}{4 s^{2} S^{4}} \sum S_{A}\left(a S^{2}-s a^{2} S_{A}\right)^{2} \\
& =\frac{1}{4 s^{2} S^{4}}\left(S^{4} \sum a^{2} S_{A}-2 s S^{2} \sum a^{3} S_{A}^{2}+s^{2} \sum a^{4} S_{A}^{3}\right) \\
& =\frac{1}{4 s^{2} S^{4}}\left(S^{4}\left(2 S^{2}\right)-2 s S^{2}\left(S^{2}\left(2 s\left(2 s^{2}-3 S_{\omega}+4 R^{2}\right)-6 R S\right)\right)+s^{2}\left(4 S^{4}\left(5 R^{2}-S_{\omega}\right)\right)\right) \\
& =\frac{R}{S}\left(9 R S+4 s\left(S_{\omega}-s^{2}\right)\right) . \tag{47}
\end{align*}
$$

Anticipating a bit the fundamentals of the next section and expressing $\left\{S, S_{\omega}\right\}$ in terms of $\{s, r\}$ in this wonderful formula

$$
\begin{equation*}
S=2 s r, \quad S_{\omega}=s^{2}-r^{2}-4 r R \tag{48}
\end{equation*}
$$

where, $r$ is the "inradius" of the triangle $A B C$, we come, after a drastic simplification, at "Euler's theorem", saying that:

$$
\begin{equation*}
I O^{2}=R(R-2 r) . \tag{49}
\end{equation*}
$$

In the file Tritangent circles we discuss this theorem from the much more elegant synthetic aspect, contrasting this computational derivation, whose real purpose was to test the calculations of section 3 .

Here we have an instance indicating the contrast of the "generality of the method" to the "elegance of the particular case". The computations with barycentrics supply a general method to calculate the distance, in principle, of any pair of remarkable points related to the triangle $A B C$ i.e. "triangle centers". The particular case though, as is here the case with the distance $|I O|$, can be alternatively handled with geometric tools and give a much deeper insight in the geometry of the triangle.

It is the genius of Euler ([BS07], [Col07]) to foresee that these two points are connected by such a simple relation as the one expressed by equation (49) and avoid some other candidates, such as, for example, the next one of $|H I|$ depending on all three $\{r, R, s\}$.

$$
\begin{align*}
H I^{2} & =\sum S_{A}\left(\frac{S_{B} S_{C}}{S^{2}}-\frac{a}{2 s}\right)^{2} \\
& =\sum S_{A}\left(\frac{S_{B}^{2} S_{C}^{2}}{S^{4}}-\frac{a S_{B} S_{C}}{s S^{2}}+\frac{a^{2}}{4 s^{2}}\right) \\
& =\sum \frac{S_{A} S_{B}^{2} S_{C}^{2}}{S^{4}}-\sum \frac{a S_{A} S_{B} S_{C}}{s S^{2}}+\sum \frac{a^{2} S_{A}}{4 s^{2}} \\
& =\frac{S_{A} S_{B} S_{C}}{S^{4}} \sum S_{B} S_{C}-\frac{S_{A} S_{B} S_{C}}{s S^{2}} \sum a+\frac{1}{4 s^{2}} \sum a^{2} S_{A} \\
& =\frac{S_{A} S_{B} S_{C}}{S^{4}}\left(S^{2}\right)-\frac{S_{A} S_{B} S_{C}}{s S^{2}}(2 s)+\frac{1}{4 s^{2}}\left(2 S^{2}\right) \\
& =S_{\omega}-4 R^{2}-2\left(S_{\omega}-4 R^{2}\right)+\frac{1}{2 s^{2}}\left(S^{2}\right) \\
& =\frac{1}{2 s^{2}}\left(S^{2}-2 s^{2}\left(S_{\omega}-4 R^{2}\right)\right) \\
& =4 R(R+r)+3 r^{2}-s^{2} . \tag{50}
\end{align*}
$$

Combining equations (43) and (50), we come to the well known "Gerretsen's inequalities" ([WZ03]), which together with "Blundon's inequalities", discussed in the file Fundamental invariants, are two important "triangle inequalities"([ea69]) for $s^{2}$.

$$
\begin{equation*}
16 R r-5 r^{2} \leq s^{2} \leq 4 R(R+r)+3 r^{2} . \tag{51}
\end{equation*}
$$

## 6 Connection with the fundamental invariants

The "fundamental invariants" of the triangle are traditionally considered to be the "halfperimeter" $s=\frac{a+b+c}{2}$, the "inradius" $r$ i.e. the radius of the inscribed circle, and the " circumradius" $R$ i.e. the radius of the circumcircle of the triangle, somewhat more extensively discussed in the file Fundamental invariants. There, among other things, are proved also the next identities, in which the sums extend over the cyclic permutations of $\{a, b, c\}$. For general trigonometric relations between the elements of a triangle see [Lon93, p.135] and [Hob18, p.155]. The basic relations are given by the next two lines.

$$
\begin{align*}
& \Delta=s r=\frac{a b c}{4 R} \text { and } S=2 \Delta=2 s r=\frac{a b c}{2 R} .  \tag{52}\\
& S_{\omega}=S_{A}+S_{B}+S_{C}=\frac{1}{2}\left(a^{2}+b^{2}+c^{2}\right)=s^{2}-r(4 R+r) \tag{53}
\end{align*}
$$

Replacing $\left\{S, S_{\omega}\right\}$ in the formulas of section 3, we find the corresponding expressions in terms of the fundamental invariants $\{s, r, R\}$, as is the case with the next examples:

$$
\begin{align*}
b c+c a+a b & =s^{2}+r(4 R+r),  \tag{54}\\
a^{2}+b^{2}+c^{2} & =2\left(s^{2}-r(4 R+r)\right),  \tag{55}\\
a^{3}+b^{3}+c^{3} & =2 s\left(s^{2}-6 r R-3 r^{2}\right),  \tag{56}\\
a^{4}+b^{4}+c^{4} & =2\left(\left(s^{2}-r^{2}-4 R r\right)^{2}-4 r^{2} s^{2}\right),  \tag{57}\\
a b(a+b)+b c(b+c)+c a(c+a) & =2 s\left(s^{2}-2 r R+r^{2}\right),  \tag{58}\\
a(b-c)^{2}+b(c-a)^{2}+c(a-b)^{2} & =2 s\left(s^{2}+r^{2}-14 R r\right), \tag{59}
\end{align*}
$$

$$
\begin{array}{ll}
a S_{a}+b S_{b}+c S_{c} & =4 s r(r+R), \\
S_{A}^{2}+S_{B}^{2}+S_{C}^{2} & =\left(s^{2}-r(4 R+r)\right)^{2}-8 s^{2} r^{2}, \\
a^{2} S_{A}^{2}+b^{2} S_{B}^{2}+c^{2} S_{C}^{2} & =8 s^{2} r^{2}\left(6 R^{2}+4 R r+r^{2}-s^{2}\right) \\
S_{A} S_{B} S_{C} & =S^{2}\left(s^{2}-(r+2 R)^{2}\right), \\
\sum a_{A}^{2} & =4 s r\left(r R(4 R+r)+s^{2}(R-2 r)\right), \\
\sum S_{A}^{2} S_{B}^{2} & =8 s^{2} r^{2}\left[s^{2}\left(4(r+R)^{2}-s^{2}\right)-r(r+2 R)^{2}(r+4 R)\right] . \tag{65}
\end{array}
$$

## 7 Orthic axis = Radical axis of circumcircle and Euler circle

Theorem 1. The radical axis of the circumcircle and the Euler circle of the triangle $A B C$ is the trilinear polar of the orthocenter $H$, called "orthic axis" of the triangle.

Figure 3: The radical axis of $\{\kappa, \lambda\}$ is the trilinear polar of $H$
The trilinear polar passes through the harmonic conjugates $\left\{P=A^{\prime}(B C), Q=B^{\prime}(C A)\right\}$ (See Figure 3). It suffices to show that the power of these points relative to the two circles is the same. This is done by a typical calculation, starting from the cosine rule, for $P$ and setting $x=P B$. The corresponding calculation for $Q$ being similar:

$$
\begin{aligned}
& A^{\prime} B=\frac{1}{a} S_{B}, A^{\prime} C=\frac{1}{a} S_{C}, \\
& \frac{P B}{P C}=\frac{A^{\prime} B}{A^{\prime} C}=\frac{S_{B}}{S_{C}} \Rightarrow x=P B=a \frac{S_{B}}{S_{C}-S_{B}} \\
& \text { power w.r. } \kappa \kappa P B \cdot P C=x(x+a)=\cdots=\frac{a^{2} S_{C} S_{B}}{\left(S_{C}-S_{B}\right)^{2}}, \\
& \text { power w.r. } \lambda \lambda \\
& \text { pA } \cdot P A^{\prime \prime}=\cdots=\frac{a^{2} S_{B} S_{C}}{\left(S_{B}-S_{C}\right)^{2}} .
\end{aligned}
$$

## 8 GHI triangle, Feuerbach point

Euler considered the problem of constructing the triangle $A B C$ from the corresponding triangle HIO. This is equivalent to the problem of constructing $A B C$ from the triangle

GHI or GIO, since each of these triangles determines the other two. The problem for GIO is discussed in the file Fundamental invariants. Here we discuss some relations con-

Figure 4: Triangle centers $F=X(11), \quad N_{a}=X(8), \quad M=X(100), \quad M^{\prime}=X(104)$
nected with these three triangles, suggested by figure 4. In this $F=X(11)$ is the "Feuerbach point" (discussed in the file Tritangent circles) of contact of the incircle $\lambda$ with the Euler circle $v$ of $A B C$. Point $N_{a}=X(8)$ is the "Nagel point" of intersection of the cevians to the contact points with the excircles of the triangle and $M=X(100), M^{\prime}=X(104)$ are the diametral points of the diameter $O N_{a}$ of the circumcircle $\kappa$ of $A B C$. The following theorem summarizes the relevant properties.
Theorem 2. With the definitions and conventions adopted so far, the following are valid properties:

1. Points $\left\{I, G, N_{a}\right\}$ are collinear and $G N_{a}=2 I G$.
2. Lines $\left\{I O, H N_{a}\right\}$ are parallel and $H N_{a}=2 I O$.
3. Lines $\left\{I F, O N_{a}\right\}$ are parallel.
4. Point $F$ is the middle of $H M^{\prime}$.
5. Points $F, G, M$ are collinear and $G M=2 F M$.
$N r-1$ is proved in the files Barycentric coordinates and Nagel point of the triangle.
$\mathrm{Nr}-2$ follows trivially since $\mathrm{GH}=2 \mathrm{OG}$.
$N r-3$ follows from the fact that the center $N$ of the Euler circle $v$ is the middle of HO , hence $|G O| /|G N|=\left|G N_{a}\right| /|G I|=2$.
$N r-4$ follows from the fact that $H$ is the homothety center of the two circles $\{v, \kappa\}$ with homothety ratio 2.
$N r-5$ is a consequence of the previous $n r$.

## 9 Third degree equation for the symbols

Using Vieta's rules, expressing the coefficients of polynomial equations

$$
a_{n} x^{n}+a_{n-1} x^{n-1}+\ldots+a_{0}=0,
$$

by means of symmetric functions of the roots ([Tur47, p.66])

$$
\sum_{i_{1}<\cdots<i_{k}} x_{i_{1}} \ldots x_{i_{k}}=(-1)^{k} \frac{a_{n-k}}{a_{n}}, \text { for } k=1, \ldots, n
$$

and the corresponding formulas for the symmetric functions of the symbols $\left\{S_{A}\right\}$, we arive at the cubic equation satisfied by these symbols:

$$
\begin{equation*}
x^{3}-S_{\omega} x^{2}+S^{2} x-S^{2}\left(S_{\omega}-4 R^{2}\right)=0 \tag{66}
\end{equation*}
$$

Transforming the equation into the "reduced" form $y^{3}+p y+q=0$ and requiring that the roots of this equation are real ([Tur47, p.121]), we arive at the condition $4 p^{3}+27 q^{2}<0$, which translates in this case to the biquadratic equation:

$$
\begin{equation*}
S^{4}+2\left[S_{\omega}^{2}-18 R^{2} S_{\omega}+54 R^{4}\right] S^{2}+S_{\omega}^{3}\left(S_{\omega}-4 R^{2}\right)<0 \tag{67}
\end{equation*}
$$

Considering this as a quadratic equation w.r. to $S^{2}$, we see that the corresponding discriminant is found to be

$$
D=4 R^{2}\left(9 R^{2}-2 S_{\omega}\right)^{3}=4 R^{2}\left(O H^{2}\right)^{3} .
$$

Thus, in order to satisfy the inequality (67), the quantity $S^{2}$ must be between the roots of the corresponding quadratic i.e. it must satisfy the inequalities:

$$
\begin{equation*}
U-2 R|O H|^{3}<S^{2}<U+2 R|O H|^{3}, \text { where } U=S_{\omega}^{2}-18 R^{2} S_{\omega}+54 R^{4} . \tag{68}
\end{equation*}
$$
